AEAddressDesc structure

#include <AppleEvents.h>

typedef AEDesc **AEAddressDesc**; address descriptor record

Every Apple event includes an attribute that contains the address of the target application. A descriptor record that contains an application's address is called an address descriptor record.The address in an address descriptor record can be specified as an application signature, a process serial number, a session reference number, a target ID record, or a data type that you define.
Like several of the other data structures defined by the
Apple Event Manager for use in Apple event attributes and Apple event parameters, an address descriptor record is identical to a descriptor record of data type AEDesc; the only difference is that an address descriptor record must always contain an application's address.
